Bios 6301: Assignment 4

Ying Ji

Grade: 49/50

Comment In the football problem you've added a requisite that there is at least 1 player in each position via the following code: x2[qb.ix, 'marg'] <- x2[qb.ix,'points'] - x2[qb.ix[max(1,posReq['qb'])*nTeams],'points'] . I did not take off for this because it was a logical assumption. But FYI, Cole's intent is to allow for zero players in a position for the fantasy team.

Due Tuesday, 01 November, 1:00 PM

$5^{n=day}$ points taken off for each day late.

50 points total.

Submit a single knitr file (named `homework4.rmd`), along with a valid PDF output file. Inside the file, clearly indicate which parts of your responses go with which problems (you may use the original homework document as a template). Add your name as `author` to the file's metadata section. Raw R code/output or word processor files are not acceptable.

Failure to name file `homework4.rmd` or include author name may result in 5 points taken off.

Question 1

15 points

A problem with the Newton-Raphson algorithm is that it needs the derivative f'. If the derivative is hard to compute or does not exist, then we can use the *secant method*, which only requires that the function f is continuous.

Like the Newton-Raphson method, the **secant method** is based on a linear approximation to the function f. Suppose that f has a root at a. For this method we assume that we have *two* current guesses, x_0 and x_1, for the value of a. We will think of x_0 as an older guess and we want to replace the pair x_0, x_1 by the pair x_1, x_2, where x_2 is a new guess.

To find a good new guess x2 we first draw the straight line from $(x_0, f(x_0))$ to $(x_1, f(x_1))$, which is called a secant of the curve $y = f(x)$. Like the tangent, the secant is a linear approximation of the behavior of $y = f(x)$, in the region of the points x_0 and x_1. As the new guess we will use the x-coordinate x_2 of the point at which the secant crosses the x-axis.

The general form of the recurrence equation for the secant method is:

$$x_{i+1} = x_i - f(x_i)\frac{x_i - x_{i-1}}{f(x_i) - f(x_{i-1})}$$

Notice that we no longer need to know f' but in return we have to provide *two* initial points, x_0 and x_1.

Write a function that implements the secant algorithm. Validate your program by finding the root of the function $f(x) = \cos(x) - x$. Compare its performance with the Newton-Raphson method – which is faster, and by how much? For this example $f'(x) = -\sin(x) - 1$.

```
#function that implements the secant algorithm
secant<-function(x_old,x,f,tol=10e-7,maxiter=1000) {
        i<-1
       while( abs(x-x_old)>tol  && i<maxiter ) {
                temp<-x
```

```
                x<-x-f(x)*(x-x_old)/(f(x)-f(x_old))
                x_old<-temp
                i<-i+1
        }

        if (i==maxiter){
                print('fail to converge')
                return(NULL)
        }else { return (x)
#print(sprintf('converges at %s',i)),used to see the process,
#but will generate too many lines if iterate 10000 times
        }
        x
}

#newton algorithm
newton <-function(guess,f,fp,tol=10e-7,maxiter=1000){
        i<-1
        while(abs(f(guess))>tol && i<maxiter){
                guess<-guess-f(guess)/fp(guess)
                i<-i+1
        }
        if (i==maxiter){
                print('fail to converge')
                return(NULL)
        }else { return (guess)
#print(sprintf('converges at %s',i)), used to see the process,
#but will generate too many lines if iterate 10000 times
        }
        guess
}
f<-function(x) cos(x)-x
fp<-function(x) -sin(x)-1
system.time(replicate(10000,secant(-10,10,f)))
```

```
##    user  system elapsed
##   0.447   0.010   0.464
```
```
system.time(replicate(10000,newton(10,f,fp)))
```

```
##    user  system elapsed
##   1.915   0.022   1.962
```
```
system.time(replicate(10000,secant(-1,1,f)))
```

```
##    user  system elapsed
##   0.335   0.006   0.344
```
```
system.time(replicate(10000,newton(1,f,fp)))
```

```
##    user  system elapsed
##   0.157   0.004   0.165
```

which is faster?
To compare the performance of secant algorithm and newton algorithm,

2

```
I get the system time of finding the root of function f 10000 times.
I found the system time actually depends on our "initial guess",
so it's hard to say whether secant or newton will be faster.
For example, I tried to use replicate 10000 times with
"secant(10,-10,f)" and "newton (10,f,fp)"", Secant method took 0.3 s,
while newton method took 1.6 s: secant is a lot faster than newton.
But if I use "secant (-1,1,f)"and "newton (1,f,fp)".
Secant took about 0.3 s (elapsed), newton took 0.15s (elaspsed):
newton is twice as fast as secant.
With Newton, we already have the derivative function.
So there won't be time cost for computing that.
But the number of iterations each methods take to
get root depends on our "initial guesses".
That can have a huge impact on how fast the method is.
```

JC Grading -1

Comment Please also include the output to show that the secant and newton rhapson algorithms converge to the same answewr.

Question 2

18 points

The game of craps is played as follows. First, you roll two six-sided dice; let x be the sum of the dice on the first roll. If x = 7 or 11 you win, otherwise you keep rolling until either you get x again, in which case you also win, or until you get a 7 or 11, in which case you lose.

Write a program to simulate a game of craps. You can use the following snippet of code to simulate the roll of two (fair) dice:

1. The instructor should be able to easily import and run your program (function), and obtain output that clearly shows how the game progressed. Set the RNG seed with `set.seed(100)` and show the output of three games. (lucky 13 points)

```r
craps<-function() {
        #i=1

        x <- sum(ceiling(6*runif(2)))
        output<-x
        if (x==7 | x==11) {
                print(output)
                return("win")
        }else {
                x_old<-x

                x <- sum(ceiling(6*runif(2)))
                output<-c(output,x)
                while (x!=7 && x!=11 ) {
                        if (x==x_old){
                        print(output)
                        return("win")
                        }   else {
                        x <- sum(ceiling(6*runif(2)))
                        output<-c(output,x)
```

```
                }
        }
        print(output)
        return("lose")
        }

    }
```

show output of 3 games

```
set.seed(100)
replicate(3,craps())
```

```
##  [1]  4  5  6  8  6 10  5 10  5  8  9  9  5 11
## [1]  6  9  9 11
## [1] 6 7
```

```
## [1] "lose" "lose" "lose"
```

1. Find a seed that will win ten straight games. Consider adding an argument to your function that disables output. Show the output of the ten games. (5 points)

```
#disout: an argument to disable output,
#if TRUE, no output, if FALSE, print output to screen, default to FALSE
craps<-function(disout=FALSE) {
        #i=1

        x <- sum(ceiling(6*runif(2)))
        output<-x
        if (x==7 | x==11) {
                return("win")
                if (disout){
                capture.output( print(output),
                file='NUL')
                }else{
                 print(output)

                }

        }else {
                x_old<-x

                x <- sum(ceiling(6*runif(2)))
                output<-c(output,x)
                while (x!=7 && x!=11 ) {
                        if (x==x_old){
                        return("win")
                        if (disout){
                        capture.output(print(output),
                        file='NUL')
                        }else{
                         print(output)
```

```
                            }
                        }   else {
                            x <- sum(ceiling(6*runif(2)))
                            output<-c(output,x)

                        }
                    }
                    return("lose")
                    if (disout){
                    capture.output(print(output),
                    file='NUL')
                    }else {
                     print(output)

                    }

                    }

}

#find the seed to win 10 straight games
res <- rep(NA, 10)
for(i in seq(1:1000)){
    set.seed(i)
    for(j in 1:10){
        res[j] <- craps(TRUE)
    }
    if('lose' %in% res == FALSE){
        print (i)
    }
}
```

```
## [1] 880
```

Question 3

12 points

Obtain a copy of the football-values lecture. Save the five 2016 CSV files in your working directory.

Modify the code to create a function. This function will create dollar values given information (as arguments) about a league setup. It will return a data.frame and write this data.frame to a CSV file. The final data.frame should contain the columns 'PlayerName', 'pos', 'points', 'value' and be orderd by value descendingly. Do not round dollar values.

Note that the returned data.frame should have `sum(posReq)*nTeams` rows.

Define the function as such (6 points):

```
# path: directory path to input files
# file: name of the output file; it should be written to path
# nTeams: number of teams in league
# cap: money available to each team
# posReq: number of starters for each position
# points: point allocation for each category
ffvalues <- function(path, file='outfile.csv', nTeams=12, cap=200, posReq=c(qb=1, rb=2, wr=3, te=1, k=1]
```

```r
points=c(fg=4, xpt=1, pass_yds=1/25, pass_tds=4, pass_ints=-2,
rush_yds=1/10, rush_tds=6, fumbles=-2, rec_yds=1/20, rec_tds=6)) {

        positions <- c('k','qb','rb','te','wr')
        csvfile <- paste('proj_', positions, 16, '.csv', sep='')
        names(csvfile)<-positions
## set path, read in CSV files
        #path<-file.path('~/Documents/biostat_computing/bios6301_homework')
        path <-'.'
        setwd(path)
        k <- read.csv(csvfile['k'], header=TRUE, stringsAsFactors=FALSE)
        qb <- read.csv(csvfile['qb'], header=TRUE, stringsAsFactors=FALSE)
        rb <- read.csv(csvfile['rb'], header=TRUE, stringsAsFactors=FALSE)
        te <- read.csv(csvfile['te'], header=TRUE, stringsAsFactors=FALSE)
        wr <- read.csv(csvfile['wr'], header=TRUE, stringsAsFactors=FALSE)

  ##add position column 'pos'
        k[,'pos'] <- 'k'
        qb[,'pos'] <- 'qb'
        rb[,'pos'] <- 'rb'
        te[,'pos'] <- 'te'
        wr[,'pos'] <- 'wr'
 ## generate list of unique column names
        cols <- unique(c(names(k), names(qb), names(rb), names(te), names(wr)))
        cols <- c(cols, 'pos')

        k[,setdiff(cols, names(k))]   <- 0
        qb[,setdiff(cols, names(qb))] <- 0
        rb[,setdiff(cols, names(rb))] <- 0
        te[,setdiff(cols, names(te))] <- 0
        wr[,setdiff(cols, names(wr))] <- 0
 ## combine dataframes by row
        x <- rbind(k[,cols], qb[,cols], rb[,cols], te[,cols], wr[,cols])
## convert stats to points: multiply certain values in 'points'
        x[,'p_fg']        <- x[,'fg']*points["fg"]
        x[,'p_xpt']       <- x[,'xpt']*points["xpt"]
        x[,'p_pass_yds']  <- x[,'pass_yds']*points["pass_yds"]
        x[,'p_pass_tds']  <- x[,'pass_tds']*points["pass_tds"]
        x[,'p_pass_ints'] <- x[,'pass_ints']*points["pass_ints"]
        x[,'p_rush_yds']  <- x[,'rush_yds']*points["rush_yds"]
        x[,'p_rush_tds']  <- x[,'rush_tds']*points["rush_tds"]
        x[,'p_fumbles']   <- x[,'fumbles']*points["fumbles"]
        x[,'p_rec_yds']   <- x[,'rec_yds']*points["rec_yds"]

Question 4

5 points

This code makes a list of all functions in the base package:

```
objs <- mget(ls("package:base"), inherits = TRUE)
funs <- Filter(is.function, objs)
```

Using this list, write code to answer these questions.

1. Which function has the most arguments? (3 points)

```
which.max(sapply(funs,function(x) length(formals(x))))
```

```
## scan
##  938
```

1. How many functions have no arguments? (2 points)

```
length(funs[(sapply(funs,function(x) length(formals(x)))==0)])
```

```
## [1] 225
```

Hint: find a function that returns the arguments for a given function.
